Second Edition: July 1992

Third Edition: January 1995

Fourth Edition: April 1997

Preface

Link Level Access for the HP 9000 (LLA/9000) is a Hewlett-Packard data communications and data management product supported on earlier HP-UX releases. The Data Link Provider Interface (DLPI) is an industry standard which defines a STREAMS-based interface to the Logical Link Control (LLC) 802.3 services.

The *LLA to DLPI Migration Guide* provides information about migrating LLA programs to DLPI programs.

This manual is organized as follows:

Chapter 1	LLA to DLPI Migration provides information about migrating programs from the HP proprietary LLA to the industry standard DLPI.
Chapter 2	LLA and DLPI Example Programs includes example programs that compare LLA and DLPI.

1

LLA to DLPI Migration

LLA to DLPI Migration

As part of Hewlett-Packard's movement toward industry standard networking, HP has discontinued the LLA/9000 product with the HP-UX 10.30 release. HP recommends that you migrate all existing applications that use LLA to the industry standard Data Link Provider Interface (DLPI). HP provides DLPI with the LAN/9000 product.

Before you begin the process of migrating your application, you may need to review the *DLPI Programmer's Guide*.

The following information explains the basic differences between LLA and DLPI. This information is the basis for performing migration.

Device Files

Device files are used to identify the LAN driver, Ethernet/IEEE 802.3 interface card, and protocol to be used. Each LAN driver/interface card and protocol combination (Ethernet or IEEE 802.3) is associated with a device file.

A network device file is like any other HP-UX device file. When you write to a network device file after opening it, the data goes out on the network, just as when you write to a disk drive device file, the data goes out onto the disk.

By convention, device files are kept in a directory called `/dev`. When the LAN/9000 product is installed, several special device files are created. Among these files are the network device files associated with the LAN interface. If default names are used during installation, these files are called `/dev/lan0` and `/dev/ether0` for IEEE 802.3 and Ethernet, respectively.

LLA requires a separate device file for every LAN interface in the system. This device file is used by LLA to uniquely identify a specific device (e.g. `/dev/lan0`).

DLPI only requires one device file (`/dev/dlpi`) to access all supported LAN interfaces. In addition, there are other device files (`/dev/dlpiX`, where `X` is 0-100), used by DLPI, to access all supported LAN interfaces. The difference between `/dev/dlpi` and `/dev/dlpiX` is clone vs. non-cloneable devices. Basically, cloneable devices give you a separate stream for each open request.

Non-cloneable devices only give you one stream no matter how many times you open the device. All of the LAN interfaces supported by HP DLPI support both cloneable and non-cloneable access.

ioctl Requests

All general control requests (i.e. protocol logging, destination addresses, multicast addresses, etc.) for LLA are issued via the `ioctl` system call.

The HP-UX `ioctl` call is used to construct, inspect, and control the network environment in which an LLA application will operate. All LLA applications must use the `ioctl` call to configure source and destination addresses before data can be sent or received using the HP-UX `read` and `write` calls.

`ioctl` requests are used in DLPI only for device specific control requests. These `ioctl` requests are not interpreted by DLPI, but passed directly to the driver for processing. All general control requests in DLPI are defined with a standard DLPI 2.0 primitive or extension. These primitives are passed to DLPI via the `putmsg` system call only.

All of the standard DLPI primitives are defined in `<sys/dlpi.h>`. The *DLPI Programmer's Guide* provides detailed descriptions of all the primitives. All HP DLPI extensions (denoted in the following table with an *) are defined in `<sys/dlpi_ext.h>`.

Table 1-1 lists LLA `ioctl` request types and their corresponding DLPI primitives.

Table 1-1

LLA ioctl and Corresponding DLPI Primitives

LLA ioctl (req type)	DLPI Primitive
LOG_TYPE_FIELD	DL_BIND_REQ or DL_SUBS_BIND_REQ
LOG_SSAP	DL_BIND_REQ or DL_SUBS_BIND_REQ
LOG_DSAP	Not required with DLPI. The destination address is specified with each data request (see Transmitting data).
LOG_DEST_ADDR	Not required with DLPI. The destination address is specified with each data request (see Transmitting data).
LOG_READ_CACHE	Not defined

LLA ioctl (req type)	DLPI Primitive
LOG_READ_TIMEOUT	Not defined
LLA_SIGNAL_MASK	Not defined
FRAME_HEADER	Frame headers are delivered with each individual packet via the control portion of the message.
LOCAL_ADDRESS	DL_PHYS_ADDR_REQ
DEVICE_STATUS	DL_HP_HW_STATUS_REQ*
MULTICAST_ADDRESSES	DL_HP_MULTICAST_LIST_REQ*
MULTICAST_ADDR_LIST	DL_HP_MULTICAST_LIST_REQ*
RESET_STATISTICS	DL_HP_RESET_STATS_REQ*
READ_STATISTICS	DL_GET_STATISTICS_REQ. This primitive returns mib and extended mib statistics for the device in one request.
LOG_CONTROL	Not required with DLPI. The control value (if any) is determined from the primitive.
RESET_INTERFACE	DL_HP_HW_RESET_REQ*
ENABLE_BROADCAST	Not defined
DISABLE_BROADCAST	Not defined
ADD_MULTICAST	DL_ENABMULTI_REQ
DELETE_MULTICAST	DL_DISABMULTI_REQ

Transmitting Data

LLA requires the user to log a destination address (LOG_DEST_ADDR) and a destination service access point (LOG_DSAP) prior to sending any data.

DLPI requires the user to specify the destination address and destination service access point (dsap) as part of the data transfer request. The combination of destination MAC address and dsap is referred to as the DLSAP address.

The DLSAP address format is basically the destination MAC address followed by the LLC protocol value. A complete description of the DLSAP address format is described in the *DLPI Programmer's Guide*.

LLA supports the `write` system call for sending data requests.

DLPI only supports the `putmsg` system call for sending data over RAW (see the *DLPI Programmer's Guide*) and connectionless mode streams. The `write` system call is only supported over connection oriented streams in the DATA_XFER state (i.e. a connection must be established).

Receiving Data

LLA does not automatically return LLC header information when packets are read by the user. The user is required to issue a separate control request (FRAME_HEADER) to get the LLC header information for the last packet received.

DLPI returns the LLC header information in the control portion of each individually received packet (i.e. DL_UNITDATA_IND, DL_XID_IND, DL_TEST_IND, etc). The user is not required to issue a separate control request to get LLC header information.

LLA only allows a maximum of 16 packets (for normal users and 64 for super users) to be queued before it starts dropping data.

DLPI will read as many packets as possible until both the stream head read queue (default is about 10k bytes) and DLPI read queue (default is about 60K bytes) fill. When both these queues are full, DLPI will begin dropping data until the queues start draining.

LLA to DLPI Migration
Receiving Data

This chapter contains two example programs.

LLA and DLPI Example Programs

The first example shows a data transfer program using DLPI. The second example shows the same type of program using LLA for comparison.

DLPI Example Program
